$$dp[1 \sim n] = 5 + \max(dp[1 \sim 4], dp[6 \sim 10])$$

we choose

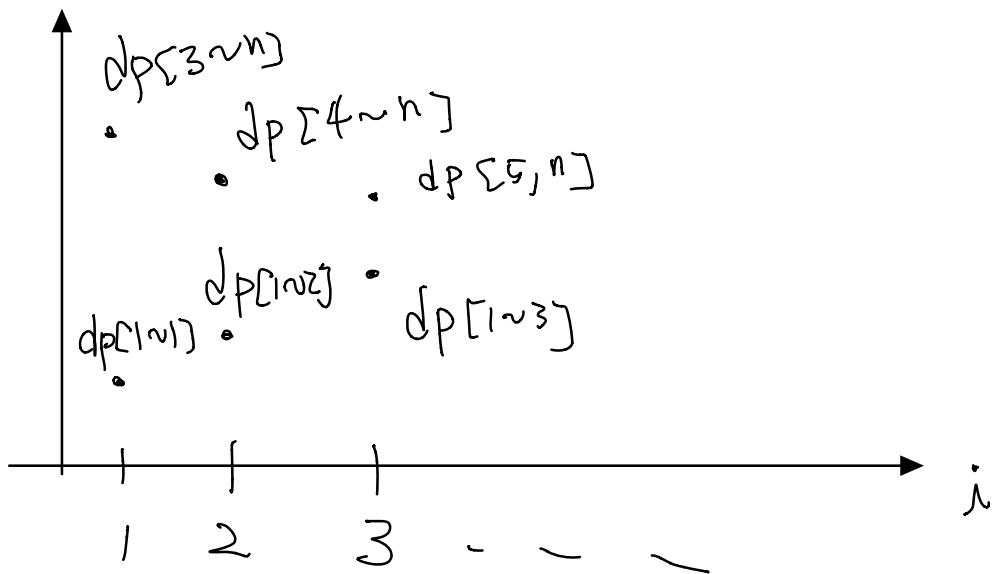

$$dp[1 \sim n] = \min_{i \in [1 \sim n]} \left(i + \max(dp[i \sim i-1], dp[i+1 \sim n]) \right)$$

$$\max \left(\begin{array}{c} dp[1 \sim 1] \\ \diagdown \quad \diagup \\ dp[3 \sim n] \end{array} \right)$$

$$\max \left(\begin{array}{c} dp[1 \sim 2] \\ \diagdown \quad \diagup \\ dp[4 \sim n] \end{array} \right)$$

$$\max \left(\begin{array}{c} dp[(\sim 3)] \\ \diagdown \quad \diagup \\ dp[5 \sim n] \end{array} \right)$$

Proof: $d_p[1 \sim 1], d_p[1 \sim 2] \dots$

$d_p[1 \sim i]$ is an
monotonic increasing (\leq)
(Proof by contradiction) sequence.

Assume

$$d_p[1 \sim k-1] > d_p[1 \sim k]$$

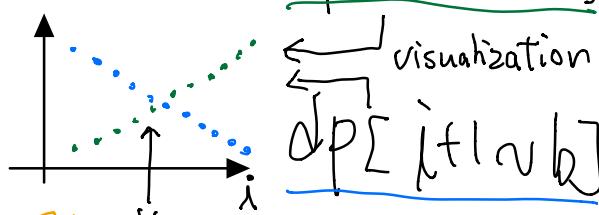

$$\textcircled{1} \textcircled{2} \dots \textcircled{k-1} \mid \overbrace{\textcircled{k}}^{\text{---}}$$

We can imagine adding k and
use $d_p[1 \sim k]$ strategy to
play the game. So $d_p[1 \sim k-1]$ becomes
smaller, violate that it already is
the minimum $\Rightarrow d_p[1 \sim k-1] \leq d_p[1 \sim k]$

We already know we want to compute:

$$dp[a \sim b] = \min_{a \leq i \leq b} \left(i + \max(dp[a \sim i-1], dp[i+1 \sim b]) \right)$$

Observe: $dp[a \sim i-1]$ is a weakly increasing (≤) seq as i increases

$dp[i+1 \sim b]$ is a weakly decreasing (≥) seq

Edge case: $b-a=1$, $\min(\text{at } dp[b \sim b], b + dp[a \sim a]) \Rightarrow \text{we set } k=a \text{ is OK}$

We must be able to find a k s.t.

$$k = \max \{ i : dp[a \sim i-1] \leq dp[i+1, b] \}$$

(i.e. $dp[a \sim k+1-1] > dp[k+1+1, b]$)

$$\begin{aligned} \text{Case 1: } a \leq i \leq k &: \max(dp[a \sim i-1], dp[i+1, b]) \\ &= dp[i+1, b] - \textcircled{1} \end{aligned}$$

$$\begin{aligned} \text{Case 2: } k < i \leq b &: \max(dp[a \sim i-1], dp[i+1, b]) \\ &= dp[a \sim i-1] - \textcircled{2} \end{aligned}$$

By ①, ②,

$dp[a \sim b]$ can be divided into 2 parts

$$\underbrace{a \leq i \leq k}_{\text{and}} \quad \underbrace{k < i \leq b}$$

$$dp[a \sim b] = \min_{a \leq i \leq b} (\dots)$$

$$= \min_{a \leq i \leq k} (\min_{a \leq i \leq k} (\dots), \min_{k < i \leq b} (\dots))$$

$$dp_1 = \min_{a \leq i \leq k} (i + dp[i+1, b])$$

$\downarrow \text{define } dp_1$

$\downarrow \text{define } dp_2$

using ①

using ②

Use deque to implement

$$dp_2 = \min_{k < i \leq b} (\bar{i} + dp[a \sim \bar{i}-1])$$

more elements

choose $\bar{i} = k+1$ (must be the minimum) \downarrow

$$= k+1 + dp[a \sim \underline{k+1-1}]$$

$$= k+1 + dp[a \sim k] \rightarrow O(1) \text{ time}$$

The remaining part is :

how to compute $\underset{①}{k}$ $\underset{②}{dP_1}$

in $O(1)$ time (or amortized $O(1)$)

For ①, observe

$$k = \max \{ i : \underbrace{dP[a \sim i-1]}_{\text{dp}[a \sim k-1]} \leq \underbrace{dP[i+1, b]}_{\text{dp}[a \sim k]} \}$$

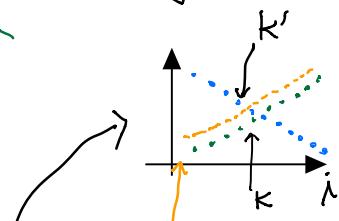

Illustration:

$$\dots \quad AI \quad \textcircled{AI} \quad \textcircled{V}$$
$$dp[k, b] \geq dp[k+1, b] \geq dp[k+2, b]$$

If a becomes smaller (say $\boxed{a' = a-1}$)

$$dP[a' \sim k-1] \geq dP[a \sim k-1]$$

$$\therefore \underset{\text{orange}}{a'} \underset{\text{green}}{a} \cdots \underset{\text{green}}{k-1}$$

Let $k' = \max\{i : dp[a' \sim i-1] \neq dp[i \sim b]\}$

Therefore, $k' \leq k$

because $\boxed{dp[a' \sim i-1]}$

becomes larger

$\Rightarrow k$ will ONLY move left (smaller)

as a becomes smaller. $\Rightarrow O(1)$

amortized,

because k
will only
step on each
position once

$$\textcircled{2} \quad dp_1 = \min_{a \leq i \leq k} (i + dp[i+1 \sim b])$$

Initial step: $a=b-1$, $dp_1 = a + dp[b \sim b]$

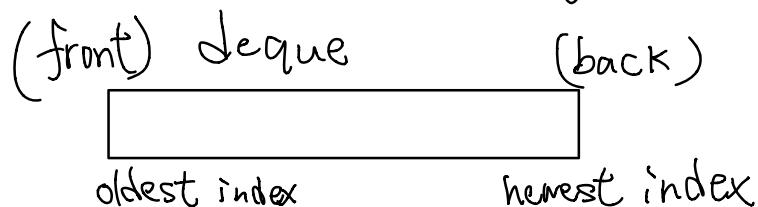

Next step: $a' = a-1$, we have to find a new k'

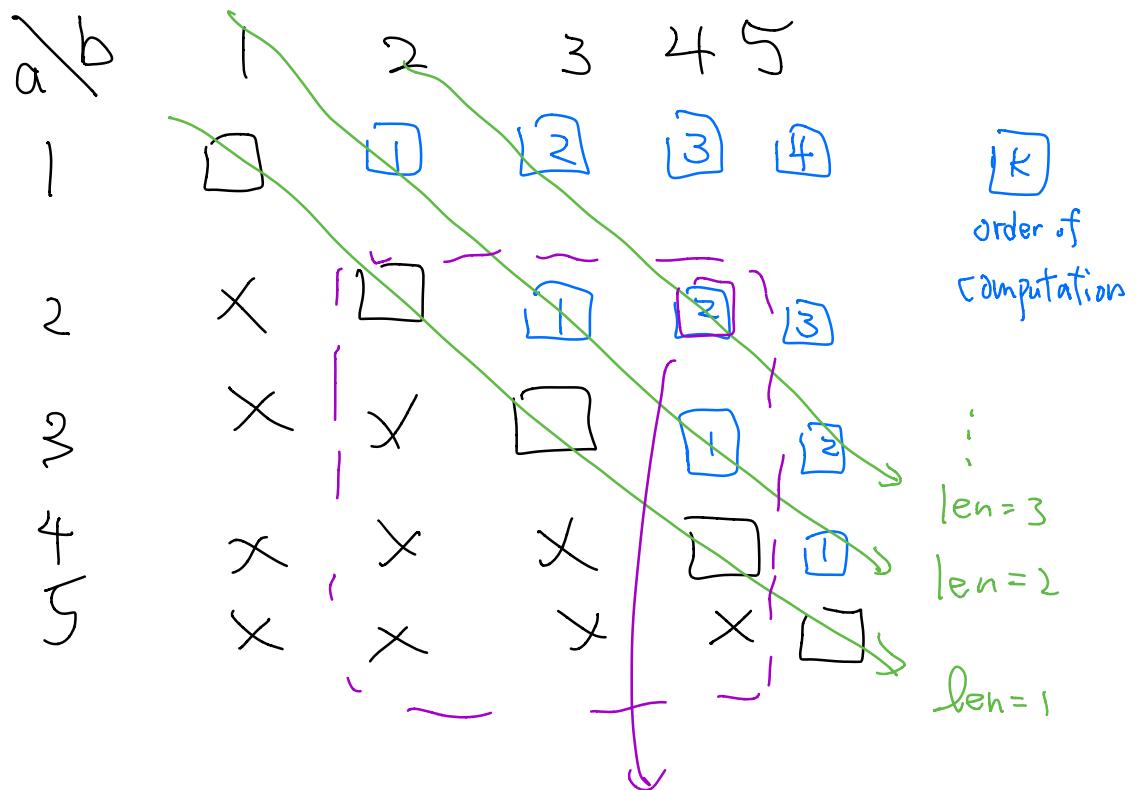

And if $k' < k$, we want to compute
 $\min_{a' \leq i \leq k'} (i + dp[i+1 \sim b])$

In $[a', k']$ window, we need to do 2 things.

- $\textcircled{1}$ Throw away $i > k'$ (from front)
- $\textcircled{2}$ put $(a', a' + dp[a'+1 \sim b])$ (to back)

in the back of an increasing deque

OR

Each element
will need values in this

region (omit X)

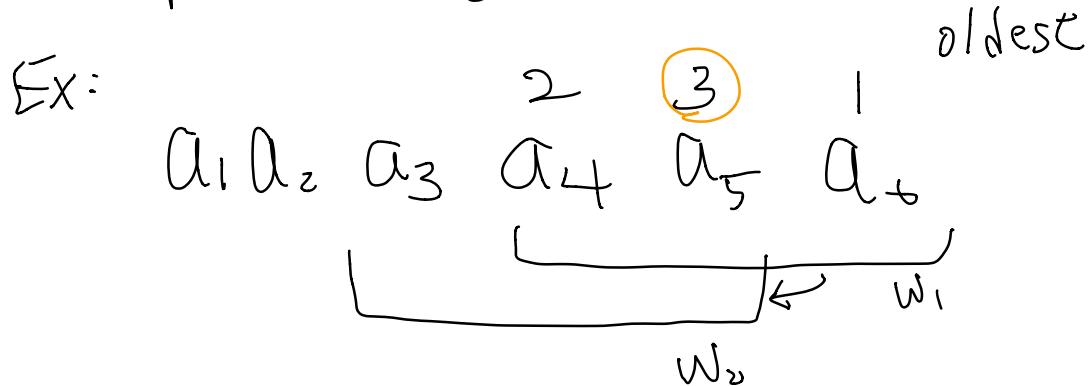

a/b	1	2	3	4	5
1	□	1	2	3	4
2	X	□	1	2	3
3	X	X	□	1	2
4	X	X	X	□	1
5	X	X	X	X	□

← Row based
should be
faster

⇒ But this

problem
cannot be solved
in row-based
(See dp1 definition)

Recap: Sliding window minimum

In w_1 :

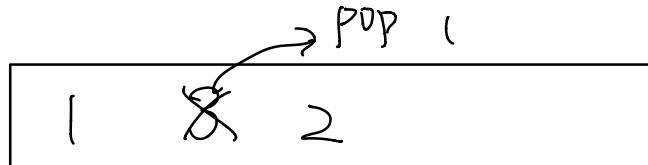

add 1

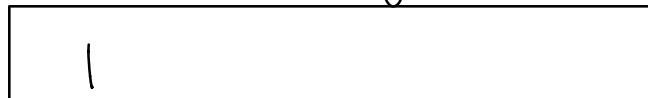

add 3

add 2

increasing values
